|--------|---|--------------------------------------|
| Dec 15 | Annual Scholarship & Officer Installation | Kellogg West Pomona, CA |
| Feb 9 | WTMS Winter Program | Huntington Gardens San Marino, CA |

Interested in hosting a program in your community? We are interested in hearing from you!
Contact heather@streettreseminar.com

MISSION STATEMENT

"To promote the advancement of urban forestry and provide a forum for tree care professionals to share their experiences, knowledge, and expertise for the benefit of the membership and the enhancement of Southern California's community forests."

VISION STATEMENT

"To enhance the health and beauty of Southern California cities by improving the quality of our community forests."

Remember to email Ann Hope at ann@mauget.com with your reservation

Tree Horror Stories w/ Susan Sims

October's meeting was hosted at the incomparable Sims Tree Learning Center in Jurupa Valley. Susan Sims shared with us some of her favorite "Tree Horror Stories" from her career. The topics covered included The Root of All Evil, Split Personalities, Man and Other Monsters, Tree Trimmers Gone Wild, and Diseases and Insects.

Photo 1
-The Root of All Evil- (*photo 1*) We saw slides illustrating the dangers of circling and girdling roots, from the early stages to advanced. Roots can cause terror in other ways, too, such as breaking and entering in to your home, wreaking all sorts of havoc in foundations, walls, floors and plumbing, to name just a few.

-Split Personalities- (*photo 2*) In this category, we saw trees damaged by their physical environment, such as a pine tree in a parking lot that may have been hit by cars parking, trees with crotch rot, and trees with hollow spots.

-Man and Other Monsters- These slides covered trees relegated to be cared for not by tree professionals, installation mistakes, careless mistakes such as neglecting to remove chains or ropes from growing trees, fire and arson, and even trees purposely poisoned by neighbors for view.

-Tree Trimmers Gone Wild- (*photo 4*) Here we had the predictable, but disappointing slides covering things like topping of trees, and trees not given the proper growing space or conditions. Proper care of your trees ensures that they will live long and healthy lives, and contribute maximum benefits back to us. Without the

Photo 2

Photo 3

proper tree-care knowledge in our Tree Trimmers, we lose.

-Diseases and Insects- (*photo 3*) The last set of slides included nutritional deficiencies, decay, fungus, and crown gall. Pests such as borers and moths were included here as well, with the PSHB being passed around so we could see how tiny these devastating creatures are.

After the presentation, those who chose to stay were treated to a tour of the property, with Susan herself leading the tour. We saw her collection of trees of all types, including many trees of different types. There are dozens of fruit trees here on site, and we were lucky to be treated to some tasting as well, enjoying a juju-bee and a vanilla bean pod amongst our group. Thank you to Susan Sims and the entire Sims team for hosting us- another great meeting! For more information on the Sims Learning Center, go to www.simstlc.com.

Fire and Bark Beetle Outbreaks: What's the Link?

Do severe wildfires make forests in the western United States more susceptible to future bark beetle outbreaks?

The answer, in a study published in the *Proceedings of the National Academy of Sciences*, is no. By leading to variability in the density and size of trees that grow during recovery, large fires reduce the future vulnerability of forests to bark beetle attacks and broad-scale outbreaks.

"Fire creates a very heterogeneous landscape," says study co-author Kenneth Raffa, professor of entomology at the University of Wisconsin-Madison. "Beetles can only reproduce in an individual tree once, so they take advantage of this patch of trees and that patch of trees as they become available, but when the number and size of trees vary a lot, it's hard for a large outbreak to develop."

Bark beetles attack trees in order to reproduce, and outbreaks occur primarily in forests in which the beetle's host trees are large and abundant. It can take decades for young, post-fire trees to reach the size they prefer. But the researchers, including UW-Madison Professor of Zoology Monica Turner, surmised that if large numbers of suitable trees became available at the same time, post-fire forests could become more susceptible to outbreaks.

However, the researchers also considered another possibility: If forests regenerate as mosaics of suitable trees on the landscape (based on size and density), though individual trees may come under attack by bark beetles, this variability might also protect the forest from broad-scale outbreaks.

The study team also includes lead author Rupert Seidl of the University of Natural Resources and Life Sciences in Vienna (who spent his sabbatical at UW-Madison in 2015) and Daniel Donato at the Washington State Department of Natural Resources, a former postdoctoral researcher in Turner's lab.

To test their questions, the team used long-term data from large and severe fires that burned 36 percent of Yellowstone National Park in 1988.

"The Yellowstone Fires are often considered to have ushered in the new era of fire activity in the west," Turner says, and she, her students and her colleagues have studied the recovery of those forests ever since.

With the data they simulated 130 years of growth following the Yellowstone Fires using a com-

puter model calibrated to the study area and used by forest and land managers around the U.S., called the Forest Vegetation Simulator.

"We use models because trees grow slowly, from a human perspective, and we won't be able to observe these changes over 100 years," Turner says.

They measured how susceptible the forests would be to bark beetle outbreaks each year following fire based on the characteristics of the dominant tree species in Greater Yellowstone: lodgepole pine and Douglas fir. They compared this to the susceptibility to outbreak assuming the forests regenerated homogeneously -- in other words, if tree density and size did not vary.

For lodgepole pine, the model showed it would take 79 years for the first post-fire stands to become highly susceptible to bark beetle outbreaks, and 115 years for half of the stands to reach vulnerability. By 130 years, 89 percent of the stands would be at risk of an outbreak.

For Douglas fir, the first stand became vulnerable to bark beetle outbreak after 99 years following the start of post-fire regeneration, according to the model. At 130 years, still just half of the stands were susceptible.

"This variation persists over 130 years," Turner says. "In contrast, the homogenous stands become vulnerable early and at the same time." The researchers documented enormous variability in the tree density, size and growth rates among areas that burned in 1988.

Turner and Raffa say land and forest managers may want to consider promoting and maintaining this natural variability to help protect forests from bark beetle outbreaks. When large numbers of trees are relatively uniform on the landscape, a sudden or even a chronic stress such as old age can make a sizeable forest resource available to beetle populations all at once.

Following fire, managers sometimes thin recovering forests, which can encourage growth of large trees and can even decrease the susceptibility of particular stands to beetle attacks. However, Raffa and Turner say that thinning employed uniformly over large areas might inadvertently increase the risk of outbreak if trees become susceptible all at once. Dense "dog-hair" stands (so-called because of the large number of short trees growing closely together, like the fur of a dog) are not usually valued, but they may play an important ecological role not previously recognized, Turner adds.

Notes from our October 2016 Meeting

Our October 2016 meeting was held at the Sims Tree Learning Center in Jurupa Valley.

Past Presidents in attendance were: Al Remyn, Kevin Holman and John Conway

Prizes were donated by: Ann Hope & RPW

Raffle Winners: Al Remyn, David Smith and Heather Crippen

Next Meeting: December 15, 2016

Join us at the Kellogg West on the Cal Poly Pomona Campus as we celebrate and honor our 2016 Scholarship recipients and install our 2017 Board of Directors.

Kellogg West @ Cal Poly Pomona
3801 W. Temple Avenue
Pomona, CA

Municipal Forestry Institute Scholarship Opportunities

Thanks to a grant from the California Department of Forestry and Fire Protection and the USDA Forest Service, SMA is offering scholarships to the Municipal Forestry Institute (MFI) at Lake Arrowhead, CA February 19-24, 2017.

Applicants must meet the following criteria:

1. Be a resident of, and employed in, the state of California, AND,
2. Demonstrate need for financial attendance in order to attend MFI.

Scholarships of \$1000 each will be awarded based on job position, geographic area represented, and date of application. When applying for MFI, please indicate you are applying for a scholarship if you meet these criteria. Application deadline is Dec 15, 2016.

Information about MFI may be found at: www.urban-forestry.com.

Questions should be emailed to: urbanforestry@prodigy.net

Fire & Bark Beetle Cont'd

In the American west, beetles and their well-adapted host trees are locked in an ever-changing arms race. Bark beetles attack a tree and the tree exudes a resin to thwart the beetle. Beetles use chemical pheromones to call in other beetles as reinforcements when they've found a good tree, but the tree subsequently changes its chemical composition to make itself less attractive and more toxic, killing some of its own tissue in the process.

"The tree launches a scorched-earth defense against the beetle, but the beetle converts the tree's toxins into attractants, like an early version of jujitsu," says Raffa. Trees that are stressed -- through drought, age, defoliation and more -- are at increased risk of attack by bark beetles, and subsequently, death. As the climate has warmed, western forests have suffered both an increase in stress and increased beetle overwintering survival, which gives advantage to the bark beetles. The forests have also experienced more frequent and severe fires.

"Climate change is creating more opportunity for beetles," Turner says. "Because temperatures are warmer, the beetles don't die off in the winter, and beetles are able to expand their range, impacting trees that are less well-adapted to defending themselves from attack." For instance, Raffa says bark beetles have "breached a historical barrier," showing up in typically cooler places like Alberta, Canada. "The boreal forest now provides a connection between the mountain pine beetle and Midwestern forests for the first time, and no one knows how quickly the beetle will advance or how big a problem it will be," he says.

Native bark beetles can present problems in Wisconsin, too. Raffa works with the Wisconsin Department of Natural Resources to refine guidelines and perform ongoing research on bark beetles in the state. Some species have long existed here, he says, but they are less aggressive than the species found out west.
